- Installation and commissioning
- Acceptance tests
- Building systems optimization and monitoring

Solar Hydrogen for buildings

Buildings have a great potential to produce their own electricity thanks to affordable photovoltaics and available area roofs and facades. To be self-sufficient over the year, the electricity converted to hydrogen by electrolysis during the sunny season can be re-used with the help of fuel cells during the winter season. Self-sufficiency of the building as well as a drastic carbon emission reduction can be obtained thanks to the introduction of PV systems coupled with Hydrogen seasonal storage. For Solar Hydrogen project, a schematic design phase is mandatory : dimensioning of the PV and storage systems, suggestion of reliable technologies available on the market, needed infrastructures and security. In this article, we introduce the case study of the first private building that will be equipped with solar hydrogen storage in western Switzerland. Dimensioning is performed with the help of the Polysun Simulation software and specific add-in modules in python.

First installation in western Switzerland

In this article, we introduce the case study of the first private building that will be equipped with solar hydrogen storage in western Switzerland. We list the steps of the schematic phase with the dimensioning methodology of a solar PV hydrogen-electrochemical system for a self-consuming building with a self-sufficient swimming pool. This concrete project also demonstrates the potential of deployment of solar hydrogen in the building market from single family homes to multi-storey buildings. The project is currently in the project phase, the PV and complete solar hydrogen system are in the purchasing phase.

The aim of the project was to maximize the self-sufficiency of an architectural building with SRE 1200 m² and 60'000 kWh electrical energy needs. In this project we have also a swimming pool that will be used over the whole year and which must be only heated by renewables. This will be achieved by installing solar PV on roof and facades, electrochemical batteries and solar hydrogen storage. Solar Thermal is also installed.

The first main step is the global building energy analysis of the building. Heating needs are calculated and dynamic simulations of the whole building systems including PV and hydrogen storage are performed with the help of **Polysun** Software (see **Figure 1**) as well as post treatment programs. The consumption will depend on building characteristics and building systems (envelop quality, HVAC heat pump geothermal, domestic hot water, appliances) and on the program usage of the owner with corresponding consumption profiles. Special programs have been developed to calculate heat losses of the swimming pool during the wintertime that can be taken into account in the Polysun model. Electrical Mobility can be introduced in the model as an additional consumer and will be part of the activity scenarios of the building.

For the dimensioning of system's power in kW (PV, charger-inverters, electrochemical batteries, electrolyser and fuel cell) as well as the electrical storage capacity in kWh, hourly simulation must be performed. The buildings is considered as consumers and producers that can exchange energy in real time within a grid network. Note that Hydrogen systems are hybrid systems always comprising an electrochemical battery absorbing fast changes and a fuel cell to manage longer run energy needs. The daily self-consumption is obtained with the help of the electrochemical storage, and the seasonal self-consumption is provided by the solar Hydrogen storage. Specific program modules are used for this task, see illustration **Figure 2**.

As a final result of the schematic design phase, the environmental indicators GWP, CED and CEDnr, including PV systems and storage systems are calculated [2]. PV technologies, type electrochemical batteries, production, life time and number of cycles are considered in the calculations. Indicators can be compared with the scenario situation without Solar Hydrogen where energy is taken from the grid and where vehicles use fossile energy. The economic analysis as well as the environmental gain should be done in this early phase to help the decision makers to go ahead with the project phase.

Schematic design phase summery

The approach for the schematic design of solar hydrogen system toward a self-sufficient building is the following :

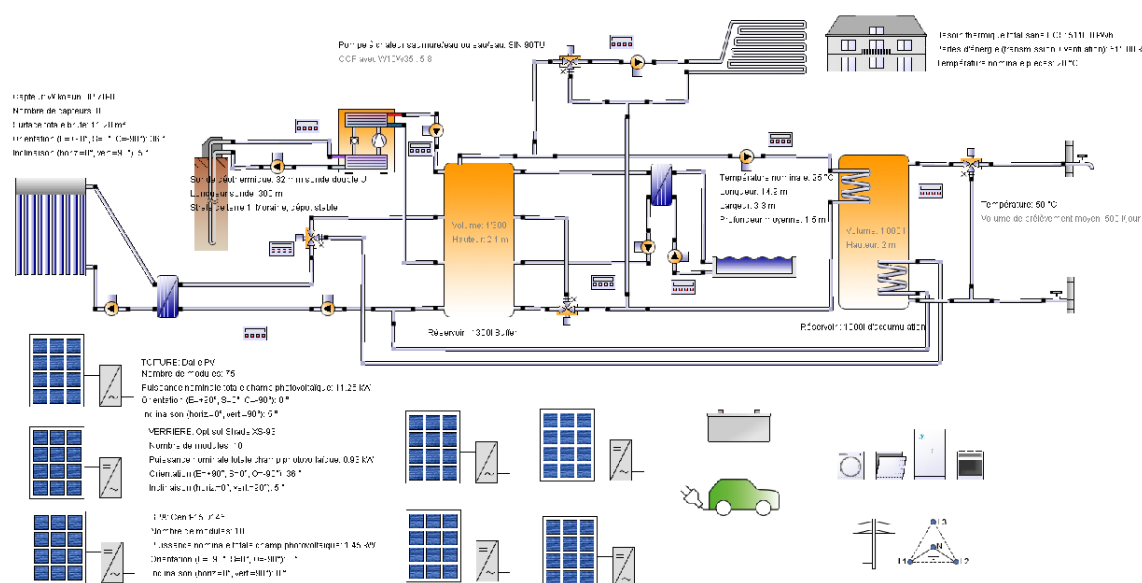

Phase 1 : Global energy analysis of the building: production - consumption - storage

- ## Phase 2 : Hourly simulations of the complete building with PV and storage systems

- ## Results and illustrations

TECPHY: your partner for Solar Hydrogen and Renewable Energy

Tecphy was founded in 2018 by Philippe Couty. It is an individual company of consultancy for the industry and the building sector developing cleantech technologies. Philippe Couty started a PhD in 1997 at EPFL in the field of cavitation in hydraulic turbines, after a master degree in physics and fluids mechanics. In 2004, he Co-founded Karmic Sarl and developed micro and nanotechnologies applications. He then decided to join the photovoltaic adventure in 2007 with the company Flexcell VHF-technologies, with mission to increase cell's efficiency of flexible solar panels using nano structuration and laser technologies. Since 2013, he pursues a carrier in R&D and industrial developments in the field of energy and industrial technologies. Between 2015 and 2017, he lead the engineering of the Swiss living challenge who won the DOE Solar Decathlon competition US 2017 Denver Colorado [1][3][4].
